#### DESCRIPTION

# METHOD FOR DETECTING GENE AFFECTED BY ENDOCRINE DISRUPTOR

Technical Field

The present invention relates to methods detecting endocrine an disruptor which influences homeostasis of a living body, and a gene influenced by said substance.

Background Art

Endocrine disruptors (often/ referred to environmental hormones) collectively refer to chemical substances released in environment /for which hormone-like activities or anti-hormone activities have been found. Altered reproductive potential /(in particular, conversion of male into female), decreased reproductive potential, decreased hatchability, decreased survival offspring, abnormal reproductive behavior and the like have been reported to be resulted from the influences of endocrine disruptors / on the ecosystem of wild animals. Decreased number of sperms, endometriosis, infertility, ovarian cancer, yterine cancer, prostatic cancer and the like have been suspected to be resulted from the influences of endocrine disruptors on human health, although they have

20

### not been demonstrated.

Substances (or groups of substances) that are considered to cause endocrine disruption are reported in the interim report (July, 1997) by "Exogenous Endocrine Disrupting Chemical Task Force" of Environment Agency. However, it is considered that the types of such substances would be further increased in the course of research and study in the future.

Known methods for determining endocrine disruptors are classified into two groups, i.e., in vitro methods and in vivo methods. Examples of the methods in the former group include a method in which a binding activity to estrogen receptor or androgen receptor is measured, and a method in which an activity of inhibiting a hormone synthesis enzyme system is measured. Examples of the methods in the latter group include a method in which production of various hormones and abnormal tissue formation in rats at different postnatal days are measured, a method in which abnormal metamorphosis in a frog is measured, and a method in which abnormal maturation in a fish is measured (Analytical Chemistry, 70(15):528A-532A (1998)).

However, it has not been clearly demonstrated to date whether or not the substances that are suspected to be endocrine disruptors with attention actually cause

15

20

25

15

20

25

endocrine disruption. Furthermore, if they cause endocrine disruption, the mechanism through which they influence as well as the amount and the length of the period of intake that might be risky have not been clearly demonstrated.

example, the current binding test hormone receptor is necessary and important as a primary screening. However, the results obtained by this method do not quarantee the identity as an endocrine disruptor. Specifically, estradiol (a / naturally occurring hormone), diethylstilbestrol (a synthetic female hormone), isoflavone (a component contained in pulses which harmless to humans) and bisphenol-A (a substance suspected to be an endocrine disruptor) bind to estrogen receptor, although the EC<sub>50</sub>/values for these substances are different each other.  $\prime$ Thus, the degree of endocrine disrupting activity of /each substance cannot be determined according to this assay method. Similarly, the activity cannot be determined according to any of the conventional methods including an assay system in which a yeast or a cultured celd is used, and a system in which uterine of a mouse is weighed.

In other words, the current methods in which a binding activity to a hormone receptor or an activity of inhibiting hormone synthesis enzyme system is measured in vitro meet a necessary condition as a method for measuring

25

5

an endocrine disruptor. However, they never meet a sufficient condition. Furthermore, methods in which influences on the growth or morphogenesis of a rat, a frog, a fish or the like are determined in vivo are less sensitive and complicated, and require a long period of time for operating a large number of samples.

In addition, although the conventional analysis methods as described above may be used to analyze the relationship between a potential endocrine disruptor and a receptor, they cannot be used to analyze the downstream signal transduction system.

As described above, it is necessary for solving problems of environmental hormones to identify endocrine disruptors and to determine the influences by the substances on the endocrine systems. Thus, methods for analyzing which signal transduction pathway is influenced by an endocrine disruptor and which substance causes endocrine disruption have been desired.

## 20 Objects of Invention

The main object of the present invention is to provide (1) a method for detecting a gene that is influenced by an endocrine disruptor; (2) a method for detecting a gene that is influenced by an endocrine disruptor which comprises measuring the expression of the

gene detected by said method; (3) a DNA array onto which a gene that is influenced by an endocrine disruptor or a DNA fragment derived from the gene is immobilized; and (4) a method for detecting a substance that potentially causes endocrine disruption.

### Summary of Invention

As a result of intensive studies, the present inventors have constructed a method for detecting many types of genes that are influenced by endocrine disruptors rapidly, with high sensitivity and simultaneously. The present inventors have found a method for detecting endocrine disruptors using a DNA array onto which said genes or fragments thereof are immobilized. Furthermore, the present inventors have constructed a method for detecting a substance that potentially causes endocrine disruption. Thus, the present invention has been completed.

In summary, the present invention relates to:

[1] a method for detecting a gene that is influenced by an endocrine disruptor, characterized in which the method comprises:

preparing a nucleic acid sample containing mRNAs, or cDNAs therefor, derived from a cell, a tissue or an organism which has been exposed to a sample containing an endocrine disruptor;

15

20

25

10

15

hybridizing the nucleic acid sample with a DNA array onto which genes which are potentially influenced by the endocrine disruptor or DNA fragments derived from the genes which are potentially influenced by the endocrine disruptor are immobilized; and

selecting a gene that is influenced by the endocrine disruptor by comparing the results with results for a nucleic acid sample prepared using a control sample;

- [2] the method according to [1] above, wherein a gene selected from the group consisting of:
- (1) a gene for a nuclear receptor or a gene related to nuclear receptor transcriptional coupling;
- (2) a gene related to kinase-type signal transduction;
  - (3) a gene related to gonad differentiation;
- (4) a gene for or related to a receptor-type
  kinase;
- (5) a gene for or related to an intermediate filament marker;
- 20 (6) a gene related to cell cycle or growth regulation;
  - (7) an oncogene, a gene related to an oncogene or a gene related to tumor suppression;
    - (8) a gene related to apoptosis;
- 25 (9) a gene related to damage response, repair or

15

### recombination of DNA;

- (10) a gene for or related to a receptor;
- (11) a gene related to cell death or differentiation regulation;
- 5 (12) a gene related to adhesion, motility or invasion of cell;
  - (13) a gene related to angiogenesis promotion;
  - (14) a gene related to cellular invasion;
  - (15) a gene related to cell-cell interaction;
  - (16) a gene for or related to a Rho family, GTPase or a regulator therefor; and
  - (17) a gene for or related to a growth factor or a cytokine,

or a DNA fragment derived from the gene is used;

- [3] a method for detecting an endocrine disruptor, characterized in which the method comprises measuring the expression of the gene detected by the method according to [1] or [2] above;
- [4] the method according to [3], wherein the endocrine disruptor is selected from ones classified into:
  - (1) dioxins;
  - (2) organochlorine compounds;
  - (3) phenols;
  - (4) phthalate esters;
- 25 (5) aromatic hydrocarbons;

15

20

- (6) pesticides;
- (7) organotin compounds;
- (8) estrogens; or
- (9) mirex, toxaphene, aldicarb or kepone;
- [5] a method for detecting a substance that potentially causes endocrine disruption, characterized in which the method comprises:

preparing a nucleic acid sample containing mRNAs, or cDNAs therefor, derived from a cell, a tissue or an organism which has been exposed to a sample that is suspected to contain a substance that potentially causes endocrine disruption;

hybridizing the nucleic acid sample with a DNA array onto which genes which are influenced by an endocrine disruptor or DNA fragments derived from the genes which are influenced by the endocrine disruptor are immobilized; and

detecting a substance that potentially causes endocrine disruption by comparing the results with results for a nucleic acid sample prepared using a control sample;

- [6] the method according to [5] above, wherein the substance that potentially causes endocrine disruption is classified into:
  - (1) dioxins;
  - (2) organochlorine compounds;
- 25 (3) phenols;

- (4) phthalate esters;
- (5) aromatic hydrocarbons;
- (6) pesticides;
- (7) organotin compounds;

10

- (8) estrogens; or
- (9) mirex, toxaphene, aldicarb or kepone;
- [7] a DNA array for detecting a gene that is influenced by an endocrine disruptor, onto which a gene that is influenced by an endocrine disruptor or a gene that is potentially influenced by an endocrine disruptor, or a DNA fragment derived from the gene is immobilized;
- [8] the DNA array according to [7] above, onto which a gene selected from the group consisting of:
- (1) a gene for a nuclear receptor or a gene related to nuclear receptor transcriptional coupling;
- (2) a gene related to kinase-type signal transduction;
  - (3) a gene related to gonad differentiation;
- (4) a gene for or related to a receptor-type kinase;
  - (5) a gene for or related to an intermediate filament marker;
  - (6) a gene related to cell cycle or growth regulation;
- 25 (7) an oncogene, a gene related to an oncogene or

15

20

25

- a gene related to tumor suppression;
  - (8) a gene related to apoptosis;
- (9) a gene related to damage response, repair or recombination of DNA;
- 5 (10) a gene for or related to a receptor;
  - (11) a gene related to cell death or differentiation regulation;
  - (12) a gene related to adhesion, motility or invasion of cell;
    - (13) a gene related to angiogenesis promotion;
    - (14) a gene related to cellular invasion;
    - (15) a gene related to cell-cell interaction;
  - (16) a gene for or related to a Rho family, GTPase or a regulator therefor; and
  - (17) a gene for or related to a growth factor or a cytokine,
  - or a DNA fragment derived from the gene is immobilized; and
  - [9] the DNA array according to [7] or [8] above, wherein the gene or the DNA fragment derived from the gene is immobilized onto a slide glass.

### Detailed Description of the Invention

(1) The method for detecting a gene that is influenced by an endocrine disruptor of the present invention

10

15

20

25

used herein, an endocrine disruptor (also referred to as an exogenous endocrine disruptor or an environmental hormone) means an exogenous substance which, when incorporated into a living body of an animal, influences a normal activity of a hormone naturally exerted in the living body. The endocrine disruptors include ones that maintain, promote or suppress a normal activity of a hormone. Substances that potentially influence a normal activity of a hormone are also included within definition.

Currently, about 70 substances (or groups substances) are suspected to have endocrine disrupting substances are classified activities. These materials for the abstract of 24th Meeting of the Japan Society for Environmental Chemistry (1998) as follows based on the methods for analyzing the corresponding substances: (1) Category 1: organochlorine compounds (e.g., general organochlorine compounds, polychlorinated biphenyl (PCB)); (2) Category 2: phenols (e.g., general phenols, bisphenol-A, 2,4-dichlorophenol, pentachlorophenol), (3) Category 3: phthalate esters (e.g., general phthalate esters); Category 4: aromatic hydrocarbons (e.g., benzo(a)pyrene, di-2-ethylhexyl adipate (DEHA), benzophenone, nitrotoluene, stylene dimer and trimer, 1,2-dibromo-3chloropropane, styrene, n-butylbenzene); (5) Category 5:

pesticides (e.g., general pesticides, 2,4,5-T (trichlorophenoxyacetic acid), 2,4-D (dichlorophenoxyacetic acid), benomyl, amitrole, methomyl); (6) Category 6: organotin compounds; (7) Category 7: estrogens; dioxins which are not classified into the above-mentioned seven categories; and substances which are excluded from the categories, i.e., mirex, toxaphene, aldicarb and kepone (chlordecone). These categories and the substances are shown in Table 1.

Table 1

Category/Substance			
Category 1	Category 3		
Polychlorinated biphenyl (PCB)	Di-2-ethylhexyl phthalate		
Polybrominated biphenyl (PBB)	Butylbenzyl phtalate		
Hexachlorobenzene (HCB)	Di-n-butyl phthalate		
Hexachlorocyclohexane	Dicyclohexyl phthalate		
Chlordane	Diethyl phthalate		
Oxychlordane	Dipentyl phthalate		
trans-Nonachlor	Dihexyl phthalate		
DDT	Dipropyl phthalate		
DDE, DDD			
Kelthane	Category 4		
Aldrin	1,2-Dibromo-3-chloropropane		
Endrin	Benzo(a)pyrene		
Dieldrin	Di-2-ethylhexyl adipate		
Endosulfan (benzoepin)	Benzophenone		
Heptachlor	4-Nitrotoluene		
Heptachlor epoxide	Stylene dimer and trimer		
Methoxychlor	Styrene		
Octachlorostyrene	n-Butylbenzene		
Category 2	Category 5		
Pentachlorophenol (PCP)	2,4,5-Trichlorophenoxyacetic		
	acid		
Alkylphenol (C5-C9)	2,4-Dichlorophenoxyacetic		
	acid		
Bisphenol-A	Amitrole		
2,4-dichlorophenol	Atrazine		

Category 5 (continued)	Category 6
Alachlor	Tributyltin
Simazine	Triphenyltin
Ethylparathion	
	Category 7
Carbaryl	
	Estradiol
Malathion	
Methomyl	
Nitrophene	Not classified into the
Trifluralin	categories
Benomyl	Dioxin
Manzeb	
(mancozeb)	Environmental hormones
Maneb	excluded from the categories
Metiram	
Metribuzin	Mirex
Cypermethrin	Toxaphene
Esfenvalerate	Aldicarb
Fenvalerate	Kepone (chlordecone)
Permethrin	
Vinclozolin	
Zineb	
Ziram	

The endocrine disruptors are not limited to those listed above. For example, diethylstilbestrol (DES) which is known to cause vaginal cancer in humans, and bisphenol-A for which an estrogen (female) activity and toxicity have been observed are considered to have endocrine disrupting activities.

10

15

20

25

These substances are known to have the following primary activities: 1) direct activities on receptors (e.g., synthetic hormone formulations, DDT, phthalate esters, etc.); 2) activities through other receptors (e.g., dioxins, etc.); 3) activities of inhibiting metabolism (e.g., steroid metabolic inhibitors, inhibitors of aromatase or 5  $\alpha$ -reductase, etc.); and 4) activities through other systems (e.g., substances that influence nervous system or immune system). Thus, their modes of actions are diverse [Kagaku (Chemistry), 53(7):12-15 (1998)].

As used herein, a gene that is influenced by an endocrine disruptor is defined as a gene of which the expression is promoted or suppressed by the above-listed endocrine disruptor as compared with a control. The number of the gene(s) may be one, or two or more. Thus, a gene for or related to an agent of which the expression is directly and/or indirectly influenced by an endocrine disruptor may be selected as the gene to be immobilized onto the DNA array of the present invention. Genes of which the expression is promoted and genes of which the expression is suppressed can be preferably used. Examples of preferable candidates for such genes (i.e., genes that are potentially influenced by endocrine disruptors) include, but are not limited to, those shown in Table 2 which are

25

5

classified as follows: (1) a gene for a nuclear receptor or a gene related to nuclear receptor transcriptional coupling (nuclear receptor or nuclear receptor transcriptional coupling); (2) а gene related to kinase-type signal transduction (kinase-type signal transduction); (3) a gene related to gonad differentiation (gonad differentiation); a gene for or related to a receptor-type kinase (receptor-type kinase); (5) a gene for or related to an intermediate filament marker (intermediate filament markers); (6) a gene related to cell cycle or growth regulation (cell cycle & growth regulators); oncogene, a gene related to an oncogene or a gene related to tumor suppression (oncogenes & tumor suppressors); (8) a gene related to apoptosis (apoptosis); (9) a gene related to damage response, repair or recombination of DNA (DNA damage response, repair & recombination); (10) a gene for or related to a receptor (receptors); (11) a gene related to cell death or differentiation regulation (cell fate & development regulators); (12) a gene related to adhesion, motility or invasion of cell (cell adhesion, motility & invasion); (13) a gene related to angiogenesis promotion (angiogenesis regulators); (14) a gene related to cellular invasion (invasion regulators); (15) a gene related to cell-cell interaction (cell-cell interactions); (16) a gene for or related to a Rho family, GTPase or a regulator

therefor (Rho family small GTPases & their regulator); and (17) a gene for or related to a growth factor or a cytokine (growth factors & cytokines). Furthermore, other genes for or related to agents of which the expression is potentially influenced by endocrine disruptors in a direct and/or indirect manner are also included in the genes that are influenced by endocrine disruptors of the present invention.

The genes that are potentially influenced by endocrine disruptors are further exemplified by the gene

for estrogen receptor, which is known to bind diethylstilbestrol, bisphenol-A, 17  $\beta$ -estradiol and the like, as well as genes involved in the signal transduction pathway for the estrogen receptor.

A gene that is influenced by an endocrine disruptor can be detected as follows.

As used herein, a DNA array refers to a support onto which a gene or a DNA fragment der ved from the gene is immobilized and includes, for example, a so-called DNA chip. Any supports which can be used for hybridization may be used. A slide glass, a silicore chip, a nitrocellulose or nylon membrane or the like is/usually used. For example, the gene or a DNA fragment thereof to be immobilized onto the support can be prepared/as follows. A primer pair for PCR amplification which is optimal for the method of the present invention can be prepared based on a base sequence identified by a GenBank accession no. assigned to a gene to be immobilized or the product of the gene using a primer analysis/construction software such as Oligo<sup>TM</sup> Primer Analysis Software (Takara Shuzo). A PCR-amplified fragment of interest can be obtained by using the primer pair and a genomic DNA, a genomic DNA library or a cDNA library as a template /according to a standard protocol attached to a commerqually available PCR kit. The resulting DNA fragment can be purified using, for example, Microcon-100 (Takara

In Iu

5

15

20

Shuzo). The purified DNA fragment can be preferably used in the method of the present invention. Furthermore, a DNA array can be prepared by immobilizing the gene or a fragment thereof onto a support according to a known method, for example, by introducing an amino group to the support. Also, a DNA array onto which gene are arrayed and immobilized at high density can be prepared by conducting the immobilization procedure using an instrument for preparing DNA arrays such as an instrument for preparing DNA chips from GMS.

The use of such a DNA array makes it possible to simultaneously measure the contents of various nucleic acid molecules in a nucleic acid sample and has the advantage that the measurement can be conducted using a small amount of a nucleic acid sample.

Any genes or DNA fragments derived from the genes are immobilized onto the DNA array used in the present invention. Preferably, genes encoding proteins that are expected to have functions related to endocrine disrupting activities or DNA fragments derived from the genes are immobilized. If a fragment is used, a fragment of, for example, about 1 kb in length can be preferably used, although the length of the fragment is not limited to specific one. The length may be shorter or longer than that described above as long as the fragment specifically

٦

20

25

hybridizes with a nucleic acid from a test sample. Examples of such genes include, but are not limited to, a gene for a hormone receptor, a gene encoding a cofactor for a receptor, a gene encoding a protein involved in signal transduction from a receptor, a gene encoding a protein involved in biosynthesis or metabolism of a hormone and an oncogene.

For example, mRNAs prepared from a cell or a tissue (organ) that is sensitive to an endocrine disruptor or cDNAs obtained by reverse transcription using the mRNAs as templates can be used as nucleic acid samples containing a gene of which the expression is altered as a result of the influence of the endocrine disruptor. Such mRNAs are obtained over time or on different days after being exposed to the endocrine disruptor.

The cell to be exposed to a sample containing an endocrine disruptor may be a cell collected from an organism, or it may be a cultured cell. The tissue is not limited to specific one as long as it is supposed to be influenced by an endocrine disruptor. Furthermore, the origin of the cell or the tissue, or the organism to be used is not limited to human. The length of the time of exposure to an endocrine disruptor may vary depending on the organism, the endocrine disruptor, the gene that is influenced by the endocrine disruptor or the like to be

used.

On the other hand, a nucleic acid sample containing mRNAs, or cDNAs therefor, similarly prepared from a cell, a tissue or an organism as a control is subjected to hybridization under stringent conditions. The nucleic acid sample can be suitably labeled as follows such that it can be readily determined whether or not the nucleic acid sample hybridizes with a DNA on a DNA array.

For example, a radioisotope, a fluorescent substance, chemiluminescent substance, an antigen recognized by an appropriate antibody or the like can be used for labeling. Alternatively, hybridization may be first conducted without labeling the nucleic acid sample, and then an intercalating substance that emits fluorescence or chemiluminescence may be used for labeling.

Hybridization of the thus obtained nucleic acid sample with the DNA on the DNA array can be conducted according to a known method. It is natural to conduct hybridization and washing steps under optimal conditions depending on the length of the DNA on the DNA array or the like. These steps can be conducted under conditions, for example, as described in Molecular Cloning, A Laboratory Manual, 2nd ed., pp. 9.52-9.55 (1989).

By comparing results of hybridization for a control nucleic acid sample with those for a nucleic acid

 5

10

15

20

25

5

sample derived from a cell, a tissue or an organism which has been exposed to a sample containing an endocrine disruptor, a gene of which the signal intensity significantly different among the two nucleic acid samples can be detected. Specifically, an array is subjected to hybridization with a nucleic acid sample labeled described above. A signal intensity of radioactivity, fluorescence, luminescence or the like for the hybridized array is detected using a specialized measuring instrument such as a chromatogram scanner or image analyzer. of which the expression is significantly altered as result of the influence of an endocrine disruptor can be detected based on the difference in the signal intensity.

The gene expression for a control nucleic acid sample can be compared on the same DNA array with that for a nucleic acid sample derived from a cell, a tissue or an organism that has been exposed to an endocrine disruptor on the same DNA array by using a multiple wavelength detecting fluorescence analyzer which is capable of detecting plural labels (e.g., two types of fluorescence). For example, a nucleic acid sample derived from a cell which has been exposed to an endocrine disruptor is fluorescence-labeled with Cy3-dUTP, whereas a control nucleic acid sample is fluorescence-labeled with Cy5-dUTP. The difference in gene expression between the two nucleic acid samples can be

10

20

25

detected as difference in color by mixing equal amounts of the nucleic acid samples and subjecting the mixture to hybridization with a DNA array. A gene of which the expression level is significantly altered as a result of the influence of the endocrine disruptor can be detected based on the results.

The gene is also useful as an index for detecting an endocrine disruptor.

is influenced by gene that an endocrine selected by comparing a signal disruptor is intensity detected as an index of expression level with that obtained using a nucleic acid sample prepared using a control sample. value is calculated example, а by dividing fluorescence signal value for a sample containing endocrine disruptor by a fluorescence signal value for a A value greater than 1.00 indicates that control sample. the gene expression is promoted by the treatment with the A value smaller than 1.00 indicates that test substance. the gene expression is suppressed by the treatment with the test substance. A value equal to 1.00 indicates that the gene is not influenced by the treatment with the test If the expression is promoted, the value is greater than 1.10, preferably 1.30, more preferably 2.00. If the expression is suppressed, the value is smaller than 0.90, preferably 0.80, more preferably 0.70.

10

15

20

25

As described above, the expression of genes that are influenced by endocrine disruptors (for example, a gene for a nuclear receptor in a cell and a number of genes involved in the downstream signal transduction pathway) can be detected simultaneously, in vitro, rapidly and with high sensitivity according the method of the to present In addition, it is possible to find involvement invention. of a known gene in a previously unknown signal transduction pathway.

(2) An endocrine disruptor can be detected using the expression of a gene that is influenced by the endocrine disruptor as an index as follows.

A DNA array, onto which a gene which has been confirmed to be influenced by an endocrine disruptor is immobilized as described above, is prepared.

A nucleic acid sample is prepared from a cell, a tissue or an organism which is suspected to be influenced by the endocrine disruptor as described above. The nucleic acid sample is then hybridized as described above. Change in gene expression can be determined based on the difference between the signal intensities. The presence of the endocrine disruptor can be determined based on the results.

In another embodiment, the presence of an endocrine disruptor can be also determined as follows. An

25

5

RNA or a DNA that competes with an mRNA for a gene that has been confirmed to be influenced by the endocrine disruptor is prepared. A competitive RT-PCR is conducted using the RNA or the DNA as an internal standard. The expression level of the influenced gene is then quantitatively determined by the competitive RT-PCR.

As described above, the presence or the absence of an endocrine disruptor can be substantially and readily judged using the expression of a gene that is influenced by a endocrine disruptor (for example, a gene for a nuclear receptor in a cell or one of a number of downstream genes) as an index according to the method of the present invention.

(3) A substance that potentially causes endocrine disruption can be detected as follows.

As used herein, a substance that potentially causes endocrine disruption means a substance that potentially influences the normal activity of a hormone which is naturally exerted in a living body. Substances of which the activities have been already confirmed and substances of which the activities have not been confirmed yet are included within the definition.

A DNA array for detecting a substance that potentially causes endocrine disruption is prepared by immobilizing in a manner as described above a gene which

has been confirmed to be influenced by an endocrine disruptor according to a method as described in (1) above.

A nucleic acid sample is prepared from a cell, a tissue or an organism which has been exposed to a sample that is suspected to contain a substance that potentially causes endocrine disruption as described above. The nucleic acid sample is then hybridized as described above. Change in gene expression can be determined based on the difference between the signal intensities. The substance can be judged as an endocrine disruptor based on the results.

A substance can be considered to be an endocrine disruptor based on the results not only in case where changes in signals are observed for all of the DNAs on the DNA array but also in case where the changes are observed for a portion of the DNAs. In particular, if the changes in signal strength are observed for a portion of the DNAs, the detection method can be optimized by further selecting the genes that are influenced by the substance action according to the method as described in (1) above such that a substance that causes endocrine disruption as the substance does can be detected more exactly.

In another embodiment, an RNA or a DNA that competes with an mRNA for a gene that has been confirmed to be influenced by the endocrine disruptor as described above

10

15

20

25

is prepared. A competitive RT-PCR is conducted using the RNA or the DNA as an internal standard. The degree of endocrine disruption can be quantitatively detected based on the expression of the gene. Any methods can be preferably used for detecting, or quantifying the expression of, a gene that is influenced by an endocrine disruptor obtained as described in (1) above as long as the methods can be used for the detection/quantification of the gene.

(4) The DNA array of the present invention

As used herein, a DNA array refers to a support onto which a gene or a fragment thereof is immobilized and includes, for example, a so-called DNA chip.

Any supports which can be used for hybridization may be used for the DNA array of the present invention. Usually, a slide glass, a silicone chip, a nitrocellulose or nylon membrane or the like is used. Preferably, a support made from a material which is non-porous and has a smooth surface (e.g., a glass such as a slide glass) can be preferably used. Any supports having surfaces onto which DNAs can be immobilized through covalent bonds or noncovalent bonds can be used. Supports having hydrophilic or hydrophobic functional groups on their surfaces preferably used. Examples of the preferable functional groups on the surfaces of the supports include, but are not

10

15

20

limited to, a hydroxy group, an amino group, a thiol group, an aldehyde group, a carboxyl group and an acyl group. The functional group may be present as a surface property of the support itself, or it may be introduced by surface treatment. Examples of supports with surface treatment include a glass treated with a commercially available silane coupling agent such as aminoalkylsilane or treated with a polycation such as polylysine or polyethyleneimine. Several treated slide glasses are commercially available.

is influenced by that an disruptor or a DNA fragment derived from the gene is immobilized onto the DNA array of the present invention. The DNA array may be a DNA microarray in which doublestranded DNAs of the genes or the DNA fragments derived from the genes are arrayed and immobilized onto the same support under denaturing conditions. At least a portion of the immobilized DNA may be single-stranded. The DNA arrav herein may be prepared by spotting double-stranded DNAs onto the same support in array under denaturing conditions. The density of the array in the DNA array of the present invention is not specifically limited. For example, a DNA array with high density such as an array onto which DNAs are immobilized at 100 dot/cm<sup>2</sup> or more can be preferably used.

The DNA fragment to be arrayed and immobilized

25

5

onto a support in the present invention is not limited to specific one. In general, a double-stranded polynucleotide of 50 bases or more in length or a derivative thereof, which is prepared by enzymatic amplification by polymerase chain reaction (PCR) or the like and converted into single-stranded DNAs or derivatives thereof by denaturing upon immobilization onto a support for immobilizing a DNA, can be preferably used. The derivative may have modification which enables the immobilization onto the surface of the support. Examples of the derivatives include, but are not limited to, a DNA into which a functional group such as an amino group or a thiol group is introduced at the 5'-terminus of the DNA.

For example, a DNA amplified by PCR or the like using a genomic DNA library or a cDNA library as a template can be used as a gene or a DNA fragment to be immobilized onto a support. An oligonucleotide synthesized based on a known nucleotide sequence can also be used. A nucleic acid other than a DNA which is known in the art to be able to be used for hybridization (for example, an RNA prepared by in vitro transcription) can be immobilized in place of a DNA. The DNA array can be prepared by immobilizing the gene or a fragment thereof onto a support according to a known method, for example, by introducing an amino group to the support. The DNA array of the present invention onto which genes are

10

15

20

25

arrayed and immobilized can be prepared by conducting the immobilization procedure using an instrument for preparing DNA arrays such as an instrument for preparing DNA chips from GMS.

A gene encoding a protein having a function involved in the exertion of an activity of a hormone, or a fragment thereof, is immobilized onto the DNA array used in the present invention. If a fragment is used, a fragment of, for example, about 100 b to about 1 kb in length can be preferably used, although the length of the fragment is not limited to specific one. The length may be shorter or longer than that described above as long as the fragment specifically hybridizes with a nucleic acid from a test Examples of such genes include, but limited to, a gene for a hormone receptor, a gene encoding a cofactor for a receptor, a gene encoding a protein related to signal transduction from a receptor, a gene encoding a protein related to biosynthesis or metabolism of a hormone, an oncogene and the like. In addition, a gene that is influenced by an endocrine disruptor, for example, obtained according to the method as described in (1) above may be immobilized. Furthermore, since all of the genes that are influenced by endocrine disruptors can be obtained according to the method as described in (1) above, a DNA array for detecting genes that are influenced by endocrine

disruptors onto which all of such genes are immobilized can be prepared.

As described above, for example, a gene for a nuclear receptor in a cell and genes related to the downstream signal transduction pathway can be detected in vitro, rapidly and with high sensitivity by using the method and the DNA array of the present invention. the presence or the absence of a substance that potentially endocrine disruption can be substantially readily judged.

The following examples further illustrate the present invention in detail but are not to be construed to limit the scope thereof.

Example 1

Genes that are potentially influenced by endocrine disruptors are shown in Table 3.

Fragments of about 1 kb that contain the 3'-untranslated regions of cDNAs for these genes were prepared as follows.

Briefly, cDNA fragments of interest were amplified by reverse transcription PCR (RT-PCR) using mRNAs from cells or tissues derived from humans or mice (Clontech) as templates. The amplified cDNAs were

10

15

20

25

confirmed to be the fragments of interest by analyzing their base sequences. The amplified fragments were recovered by ethanol precipitation and dissolved in 10 mM carbonate buffer (pH 9.5) at a concentration of 1  $\mu$ M. In addition,  $\beta$ -actin gene as a housekeeping gene and a plasmid pUC18 as a negative control were similarly prepared. These fragments were spotted onto a slide glass with introduced amino groups (Sigma) using an instrument for preparing DNA chips (GMS) and fixed by UV irradiation. The slide glass was washed with 0.2% SDS followed by distilled water and dried to prepare a DNA array.

Example 2

(1) Administration into mouse

group with endocrine disruptor administration and a group without administration. Diethylstilbestrol (DES), which potentially causes endocrine disruption, was intravenously injected into each mouse in the group with administration at 0.1 mg/mouse/day for 2 days. Ovaries were removed on day 4, and mRNAs were prepared using an mRNA extraction kit (Qiagen).

cDNAs synthesis reactions were carried out using mixtures each containing about 3  $\mu g$  of the mRNA, oligo-dT primer, Cy3-dUTP (Amersham) for the group with administration or Cy5-dUTP (Amersham) for the group without

10

15

20

administration, dNTPs and reverse transcriptase (Gibco-BRL). The mixtures were subjected to gel filtration, concentrated under reduced pressure and dissolved in  $4 \times SSC/0.2\%$  SDS to prepare fluorescence-labeled cDNAs.

(2) Treatment of cultured cells

Human breast cancer MCF-7 cells were grown in DME medium containing 5% fetal bovine serum (FBS). After trypsinization,  $2 \times 10^5$  cells were placed in each well of a The cells were incubated in the 12-well culture plate. same medium for 24 hours. After the medium was removed, the cells were cultured for 72 hours in DME containing 5% human serum from which steroid hormones had been removed by treatment with activated carbon-dextran in the presence absence 17-ß estradiol or of concentration of 10 pM. The cells were recovered, and mRNAs were extracted as described in Example 2-(1).

cDNAs synthesis reactions were carried out using mixtures each containing about 3  $\mu g$  of the mRNA, oligo-dT primer, Cy3-dUTP for the cells exposed to 17- $\beta$  estradiol or Cy5-dUTP for the cells not exposed to 17- $\beta$  estradiol, dNTPs and reverse transcriptase (Gibco-BRL). The mixtures were subjected to gel filtration, concentrated under reduced pressure and dissolved in 4 x SSC/0.2% SDS to prepare fluorescence-labeled cDNAs.

(3) Hybridization of labeled cDNA with DNA array

10

Equal volumes of the Cy3-labeled cDNA and the Cy5-labeled cDNA as prepared in (1) above were mixed together and heat-denatured. 5 µl of the mixture was dropped onto the DNA array as prepared in Example 1. cover glass was placed on the mixture and the sides of the cover glass were sealed with a film. After incubation at 40-45°C for 10 hours, the cover glass was removed. array was washed in 0.2 x SSC/0.1% SDS for 30 minutes and in 0.2 x SSC for 30 minutes, and then air-dried. fluorescent signals from the respective spots on the DNA array were analyzed using a microarray scanner (GMS). Furthermore, similar procedure was carried out for the labeled cDNAs obtained in (2) above.

As a result, significant changes in signals were observed for the ovary from the mouse administered with DES and MCF-7 cells exposed to  $17-\beta$  estradiol. Thus, genes that were influenced by endocrine disruptors could be detected.

Example 3

(1) Preparation of DNA array

33 genes were selected from the genes listed in Table 3 in Example 1. The selected genes are shown in Table 4. β-Actin gene and a plasmid pBR322 were used as a housekeeping gene and as a negative control, respectively.

20

25

described in Example 1, and spotted to prepare a DNA array.

Genes for cathepsin G, NGF receptor and CSF1 receptor were amplified using primers for the respective genes contained in Human UniGene DNA set (Research Genetics).

5 (2) Examination of influence by endocrine disruptor

Influences by treatment with various endocrine disruptors for 2 or 24 hours on cultured cells were examined.

Treatment for 2 hours: Human breast cancer MCF-7 cells were grown in DME medium containing 10% fetal bovine After trypsinization, 2 x 106 cells were serum (FBS). The cells were cultured for 24 placed in a 10-cm dish. hours in DME medium containing 5% fetal bovine serum from which steroid hormones had been removed by treatment with activated carbon-dextran. After removing the medium, the cultured for 2 hour in the same cells were medium containing 10 nΜ  $17-\beta$ estradiol  $(E_2)$ , 10 diethylstilbestrol (DES) or 5 µM bisphenol-A (BisA). control, cells which were cultured in the absence of such a chemical substance were similarly prepared. The treated cells were recovered, and total RNAs were extracted as described in Example 2(1).

Treatment for 24 hours: Human breast cancer MCF-7 cells were grown in DME medium containing 10% fetal bovine

10

20

25

serum (FBS). After trypsinization, 2 x 10<sup>6</sup> cells were placed in a 10-cm culture dish. The cells were incubated for 24 hours in the same medium. After removing the medium, the cells were cultured for 24 hours in DME containing 5% human serum from which steroid hormones had been removed by treatment with activated carbon-dextran in presence of 10 nΜ 17-β estradiol  $(E_2)$ diethylstilbestrol (DES) or 5 µM bisphenol-A (BisA). As a control, cells which were cultured in the absence of such a chemical substance were similarly prepared. The treated cells were recovered, and total RNAs were extracted as described in Example 2(1).

- (3) The total RNAs as prepared in (2) above were treated with DNase. Reaction mixtures each containing about 100 to about 300  $\mu g$  of the total RNA, 10  $\mu l$  of 10 xAMV buffer (Life Science) and 10 U of DNaseI (Takara Shuzo) in a volume of 12 µl were prepared, incubated at 37°C for 10 minutes, extracted twice with phenol/chloroform, and then subjected ethanol precipitation. to The concentrations of the resulting total RNAs were determined using portions thereof.
- (4) Reverse transcription reaction was carried out using one of the total RNAs as prepared in (3) above. The composition of the reaction mixture was as follows.

Reaction mixture A: about 130 µg of the total RNA,

10

15

20

10  $\mu g$  of oligo-dT primer (Takara Shuzo) and 20  $\mu l$  of water treated with diethylpyrocarbonate (DEPC, Wako Pure Chemical Industries).

Reaction mixture B: 12  $\mu$ l of 5 x AMV RTase buffer (Life Science), 0.5 mM each of dATP, dCTP and dGTP, 0.2 mM dTTP, 60 U of RNase inhibitor (Takara Shuzo) and 0.1 mM Cy3-labeled dUTP (Amersham Pharmacia).

The reaction mixture A was incubated at 70°C for 10 minutes and then cooled on ice. The reaction mixture B was added thereto, and the resulting mixture was incubated at 42°C for 5 minutes. About 60 U of AMV RTase (Life Science) was added thereto. DEPC-treated water was further added to make the final volume to 60 µl. The resulting RT reaction mixture was incubated at 42°C for 70 minutes. 7.5  $\mu l$  of 500 mM EDTA solution and 15  $\mu l$  of 1 M sodium hydroxide were added to the reaction mixture. The mixture was incubated at 60°C for 1 hour to degrade the template RNA. After cooling to room temperature, 37.5 µl of 1 M tris-hydrochloride (pH 7.5) was added to the mixture. solution was concentrated to 20 µl using Microcon YM-30 (Millipore), 200 µl of 10 mM tris-hydrochloride containing 1 mM EDTA was added thereto, and the resulting mixture was then concentrated to 20 µl. The thus obtained Cy3-labeled cDNA solution was used for the subsequent hybridization.

(5) The Cy3-labeled cDNA as prepared in (4) above

nocousta nuon

5

10

15

was heat-denatured, and the whole solution was dropped onto the DNA array as prepared in (1) above. A cover glass was placed on the spotted solution and the sides of the cover glass were sealed with a film. After incubation at 40-45°C for 10 hours, the cover glass was removed. The DNA array was washed in 0.2 x SSC/0.1% SDS for 30 minutes and in 0.2 x SSC for 30 minutes, and then air-dried. The fluorescent signals from the respective spots on the DNA array were analyzed using a microarray scanner (GMS). Representative values each obtained by dividing a fluorescence signal value for a sample treated with one of the substances by a fluorescence signal value for a control sample are shown in In Table 5, a value greater than 1.00 indicates Table 5. that the gene expression is promoted by the treatment with A value smaller than 1.00 indicates that the gene expression is suppressed by the treatment with the A value equal to 1.00 indicates that the gene substance. is not influenced by the treatment with the test substance.

In many cases, abnormal reproduction in wild animals and reduced spermatogenesis in humans presumably caused by disruption by endocrine disrupting activities are considered to be due to suppression or interruption of signals for endocrine action at a certain stage. Therefore, it is considered that genes of which the expression is suppressed when compared with the expression in control cells should be noticed in addition to overexpressed genes. For example, among the genes used in this example, promotion of the expression of many genes that are

considered to be closely related to the action of estrogen

10

15

20

25

(e.g., genes for p300/CBP, ACTR, RIP 140, TIF2, receptor and VEGF receptor) by stimulation with E, was observed as shown in Table 5, although little is known about the pathway, the mechanism or the like. The treatment with DES, which causes endocrine disruption, for 24 hours activated almost all of the genes other than c-Myc. Suppression of the expression of the genes for N-CoR/SMRT 70 (nuclear receptor or nuclear receptor transcriptional coupling), p38 gamma (data not shown) and JNK2 (kinase-type signal transduction), and PDGF receptor (receptor-type kinase) was observed for the treatment with DES for 2 hours. On the other hand, the treatment with BisA, which is suspected to have an endocrine disrupting activity, for 2 hours suppressed the expression of the (nuclear receptor or nuclear receptor genes for ACTR transcriptional coupling) and VEGF receptor (receptor-type kinase). The influence by the treatment with BisA on the genes was considered to be less than that observed for the stimulation with DES. The treatment with BisA for 24 hours suppressed the expression of the genes for JNK2 and BMK2 (kinase-type signal transduction), and VEGF (receptor-type kinase). Thus, control of gene expression by BisA treatment in a manner different from that observed

for the stimulation with DES was observed.

As described

10

15

20

25

above, the use of the chip of the present invention provides a method in which significant variation of signals for expression depending on the substances used for treatment and the length of treatment time is observed. A gene that is influenced by an endocrine disruptor, in particular, of which the expression is suppressed by an endocrine disruptor, could be clearly detected.

## Industrial Applicability

As described above, the method of the present invention is excellently effective in that it can detect a number of genes that are influenced by endocrine disruptors simultaneously, in vitro, rapidly and with high sensitivity. Furthermore, the present invention provides a DNA array which can be used to detect genes that are influenced by endocrine disruptors rapidly and with high sensitivity. The method of the present invention is also useful for detecting a gene involved in a previously unknown signal transduction pathway. In addition, the present invention is excellently effective in that the presence or the absence of an endocrine disruptor or a substance that potentially causes endocrine disruption can be judged using the expression of a number of genes that are influenced by endocrine disruptors obtained according to the method of the present invention as an index.
